Department of Computer Engineering

Aim: Analyze the Titanic Survival Dataset and apply appropriate Regression Technique.

Objective: Able to perform various feature engineering tasks, apply logistic regression on the given dataset and maximize the accuracy.

Theory:

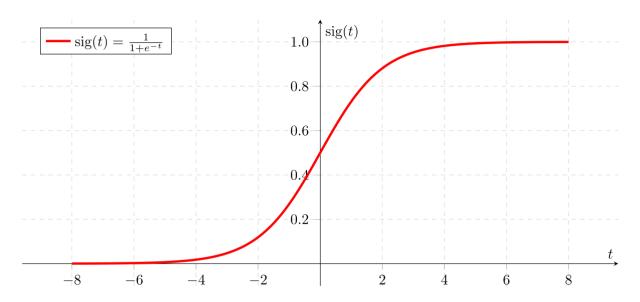

Logistic Regression was used in the biological sciences in early twentieth century. It was then used in many social science applications. Logistic Regression is used when the dependent variable(target) is categorical and is binary in nature. In order to perform binary classification the logistic regression techniques makes use of Sigmoid function.

For example,

To predict whether an email is spam (1) or (0)

Whether the tumor is malignant (1) or not (0)

Consider a scenario where we need to classify whether an email is spam or not. If we use linear regression for this problem, there is a need for setting up a threshold based on which classification can be done. Say if the actual class is malignant, predicted continuous value 0.4 and the threshold value is 0.5, the data point will be classified as not malignant which can lead to serious consequence in real time.

A STAVAROUTH IN THE STATE OF TH

Vidyavardhini's College of Engineering & Technology

Department of Computer Engineering

From this example, it can be inferred that linear regression is not suitable for classification problem. Linear regression is unbounded, and this brings logistic regression into picture. Their value strictly ranges from 0 to 1.

Dataset:

The sinking of the Titanic is one of the most infamous shipwrecks in history.

On April 15, 1912, during her maiden voyage, the widely considered "unsinkable" RMS Titanic sank after colliding with an iceberg. Unfortunately, there weren't enough lifeboats for everyone onboard, resulting in the death of 1502 out of 2224 passengers and crew.

While there was some element of luck involved in surviving, it seems some groups of people were more likely to survive than others.

In this challenge, we ask you to build a predictive model that answers the question: "what sorts of people were more likely to survive?" using passenger data (ie name, age, gender, socioeconomic class, etc).

Variable	Definition	Key
survival	Survival	0 = No, $1 = Yes$
pclass	Ticket class	1 = 1st, $2 = 2$ nd, $3 = 3$ rd
sex	Sex	
Age	Age in years	
sibsp	# of siblings / spouses aboard the Titanic	
parch	# of parents / children aboard the Titanic	
ticket	Ticket number	
fare	Passenger fare	
cabin	Cabin number	
embarked	Port of Embarkation	C = Cherbourg, Q = Queenstown, S = Southampton

Vidyavardhini's College of Engineering & Technology

Department of Computer Engineering

Variable Notes

pclass: A proxy for socio-economic status (SES)

1st = Upper, 2nd = Middle, 3rd = Lower

age: Age is fractional if less than 1. If the age is estimated, is it in the form of xx.5

sibsp: The dataset defines family relations in this way...,

Sibling = brother, sister, stepbrother, stepsister

Spouse = husband, wife (mistresses and fiancés were ignored)

parch: The dataset defines family relations in this way...

Parent = mother, father

Child = daughter, son, stepdaughter, stepson

Some children travelled only with a nanny, therefore parch=0 for them.

Analyze the Titanic Survival Dataset and apply appropriate regression technique Code:

```
#Code
```

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from sklearn.model_selection import train_test_split
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score
```

Data Collection & Processing

```
# load the data from csv file to Pandas DataFrame
titanic_data = pd.read_csv('/content/train.csv')
```

printing the first 5 rows of the dataframe
titanic_data.head()

8		PassengerId	Survived	Pclass	Name	Sex	Age	SibSp	Parch	Ticket	F

Conclusion:

- 1. What are features have been chosen to develop the model? Justify the features chosen to determine the survival of a passenger.
 - Features have been chosen based on the intuition that they could be significant factors influencing a passenger's survival. They represent a combination of socioeconomic status, family relationships, gender, and age. The choices are justified by historical knowledge of the Titanic disaster and how different groups of passengers were treated during the evacuation
- 2. Comment on the accuracy obtained.
 - The accuracy obtained from the logistic regression model applied to the Titanic Survival Dataset. Training Data Accuracy: The accuracy score on the training data is approximately 80.76%. This means that the model correctly predicts the survival status of around 80.76% of the training data samples. Test Data Accuracy: The accuracy score on the test data is approximately 78.21%. This represents the model's ability to generalize its predictions to new, unseen data.
